

Using System Dynamics to Understand Disruption:

Part 1: Sports over IP – a practical case

Emmanuel Blain
MIT

Outline

Two uses of System Dynamics as a tool to capture the dynamic complexity of the environment:

- 1. Sports over IP – a practical case** (Emmanuel Blain)
 - Rationale for use of System Dynamics in the SpoIP framework
 - Model: Block representation and Design choices
 - Results and prospective

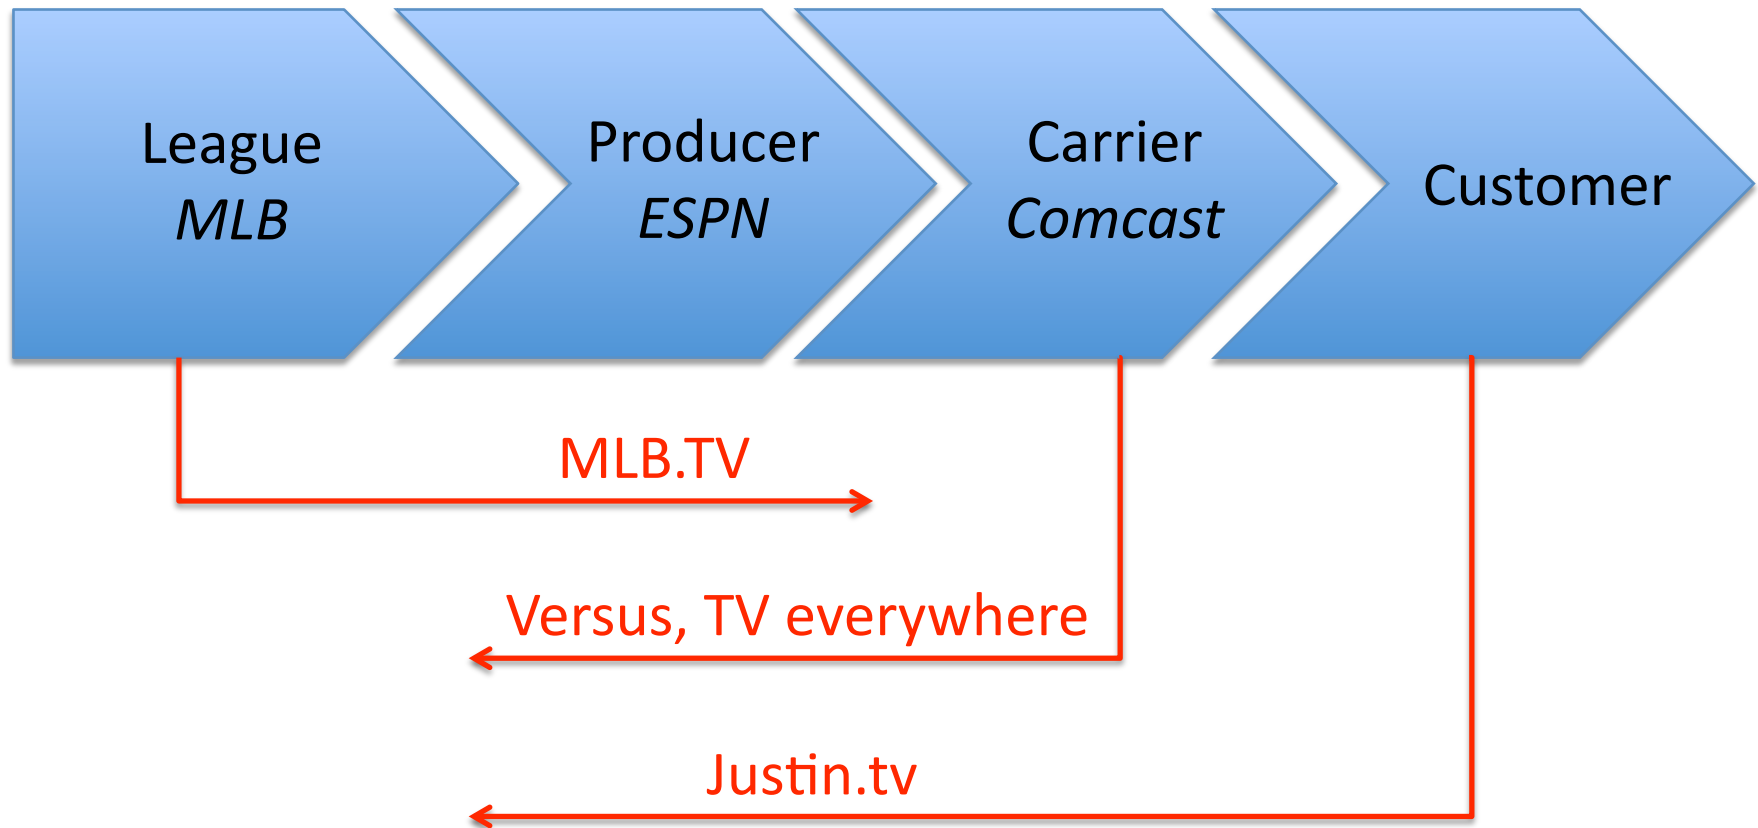

- 2. A general model for Technology and Industry Disruption**
(Chintan Vaishnav)

The SD standard method

1. Problem articulation
2. Reference modes (“triggers” in the toolkit)
3. Formulation of Dynamic Hypotheses and Causal loop diagrams
4. Formulation of the stock & flow model
5. Testing
6. Policy design and evaluation

From Sternman (2000)

Quick recap of the SpoIP issue

And a lot more complexity added by regulation, historical bonds, etc...

A trans-disciplinary problem

Dealing with the question requires to look more closely at:

- The historical roots of the existing business models
- The existing mechanics in the Sports broadcasting industry
- The technical requirements for “Sports over IP”
- The regulation in vigor (and the trends for the future)

Methodology: System Dynamics

System Dynamics is a tool of choice:

- Multi-disciplinary problem
- Dynamic problem, lots of “What if?” questions
- Behavioral factors are inherently part of the problem
- We do not try to forecast, but study interplays between stakeholders

Aim: study the technological and regulatory conditions under which the market will tip toward a predominance of broadcasters or content owners

SD model for SpolP

Dynamics of supply and demand in the sports broadcasting market

AND

Competitive model between:

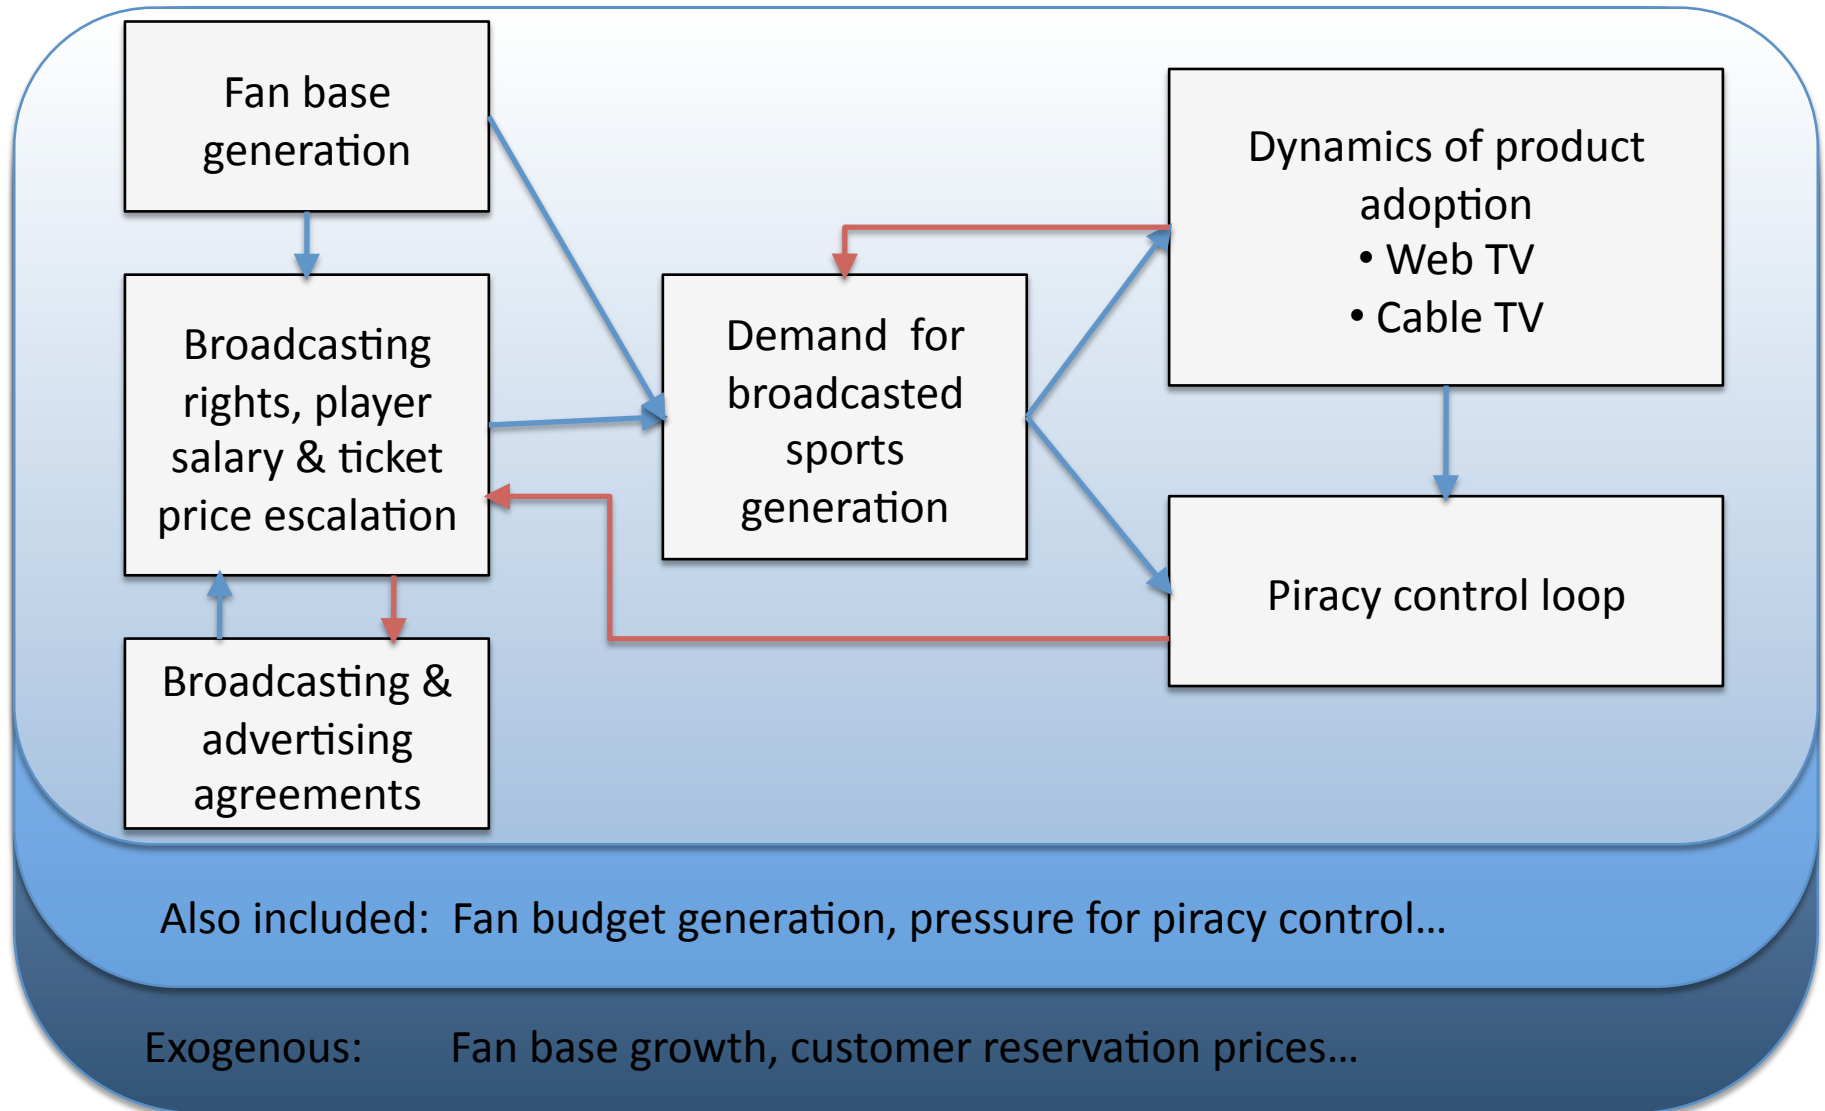

Cable TV

- Operated by legacy carriers.
- Revenues depend on # of viewers, from subscription and ads.
- Incumbent – customer base is large, price is low, quality is high

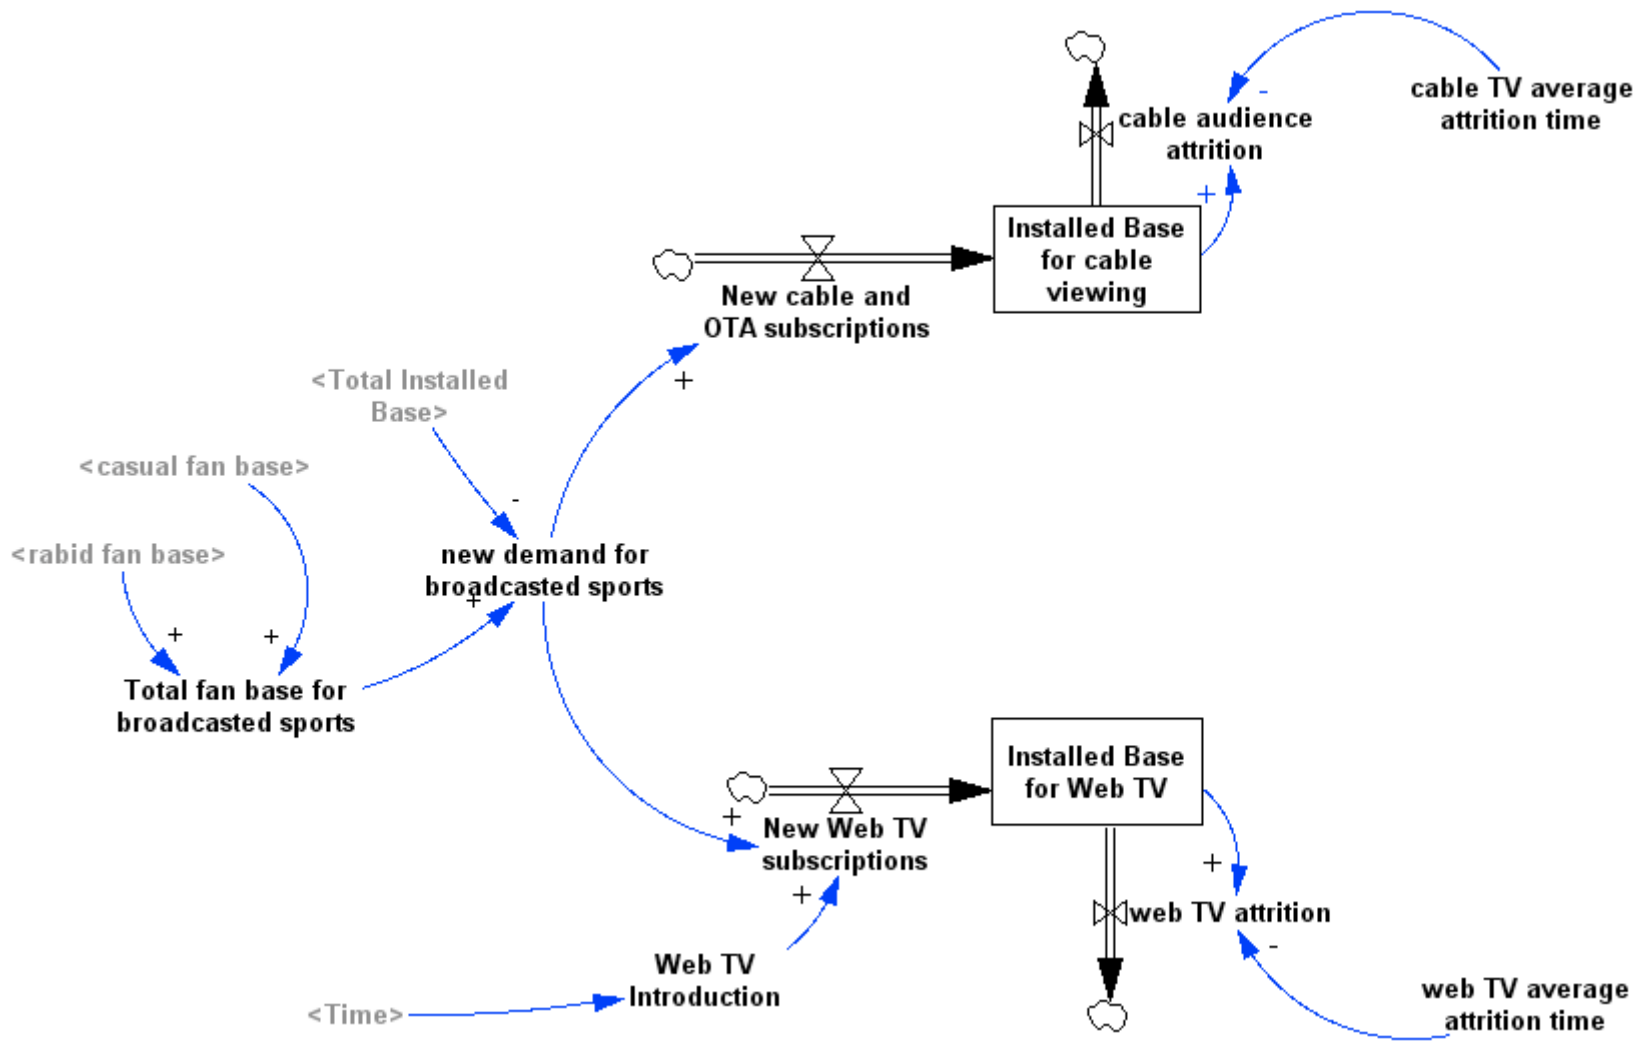

MLB.TV

- Operated by league itself.
- Revenues come from a flat subscription fee
- Entrant – customer base is small, price is rather high, but potential for quality and variety is higher than for cable.

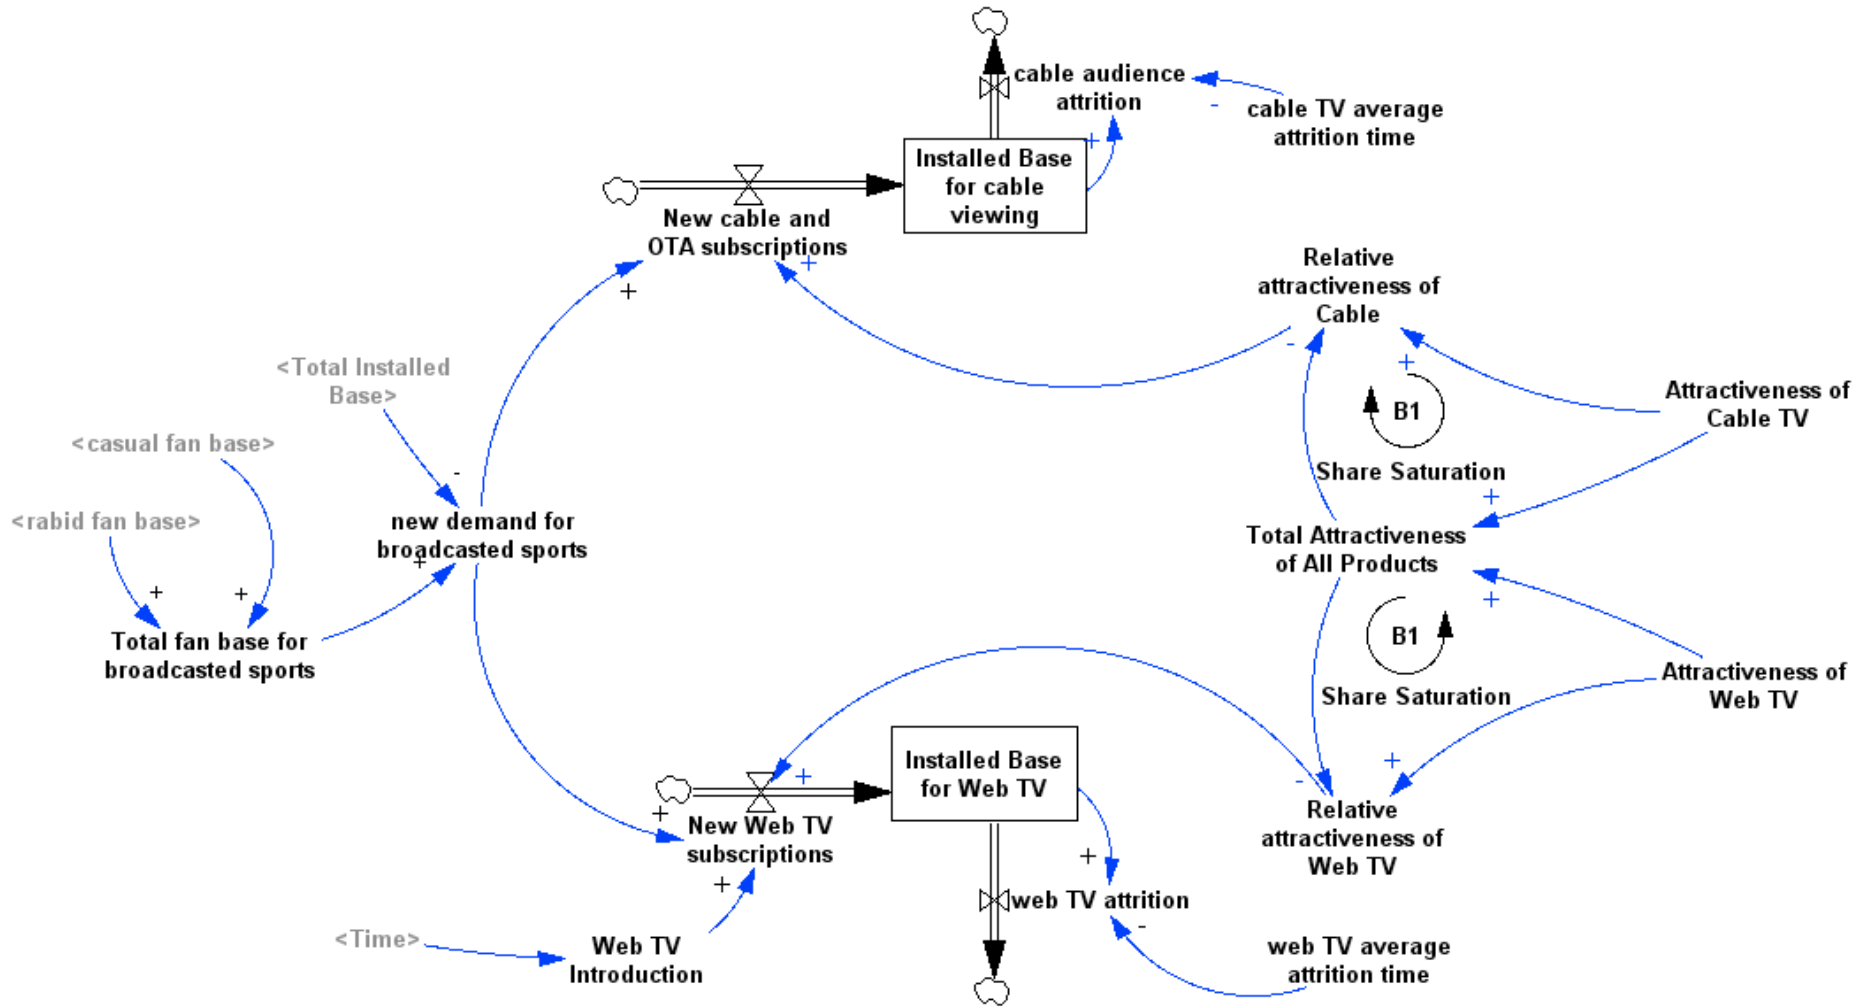

Block view of the model

Example: Dynamics of product adoption

Dynamics of product adoption

Dynamics of product adoption

What makes a sports viewing package attractive ?

Already implemented:

- Price
- Quality of content
- Variety of content

All the implemented factors have the same weight on attractiveness, and are normalized on a scale from 0 to 1.

Not implemented :

- Service uptime (may be an issue for Web TV)
- Blackouts
- Ease of use
- Network effects

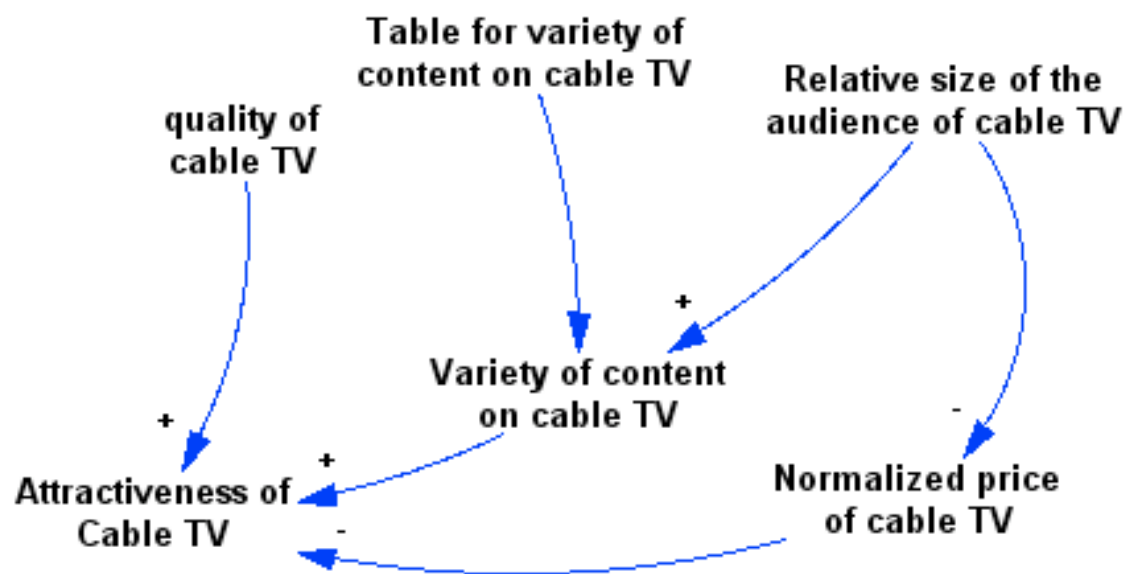

Dynamics of product adoption

Hypotheses for Cable TV:

- Cable is a MATURE technology
Quality is fixed at 0.5 (quality for Web TV varies from 0 to 1)
- Variety of content only slowly varies as long as the market share is above a threshold (incumbent “rigidity”)
- Price depends on the installed base – to a certain extent

$$\text{Attractiveness} = \text{Quality} * \text{Variety} * \text{Normalized price}$$

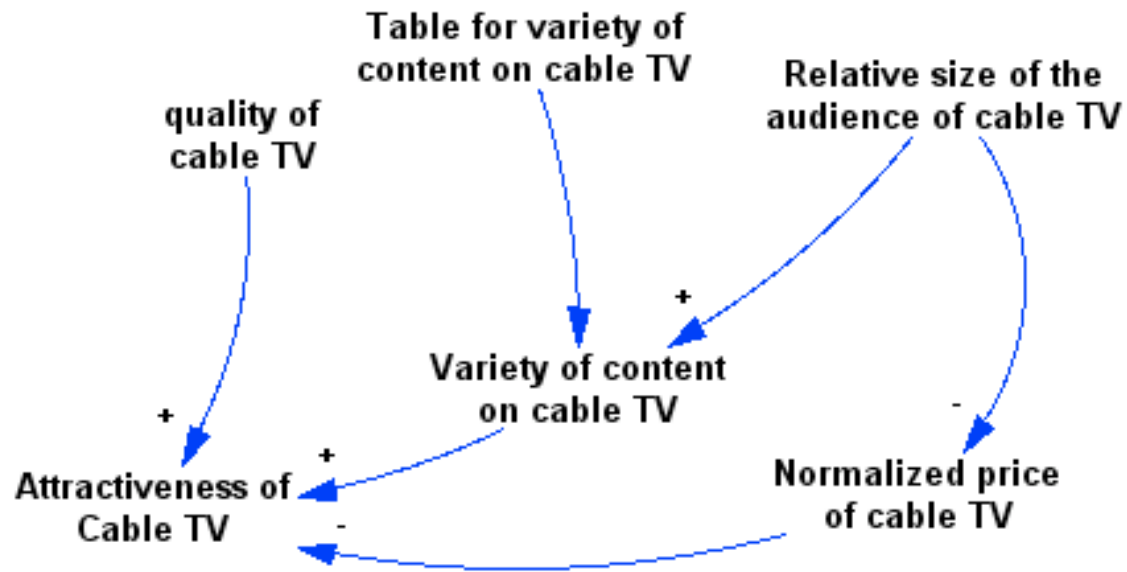

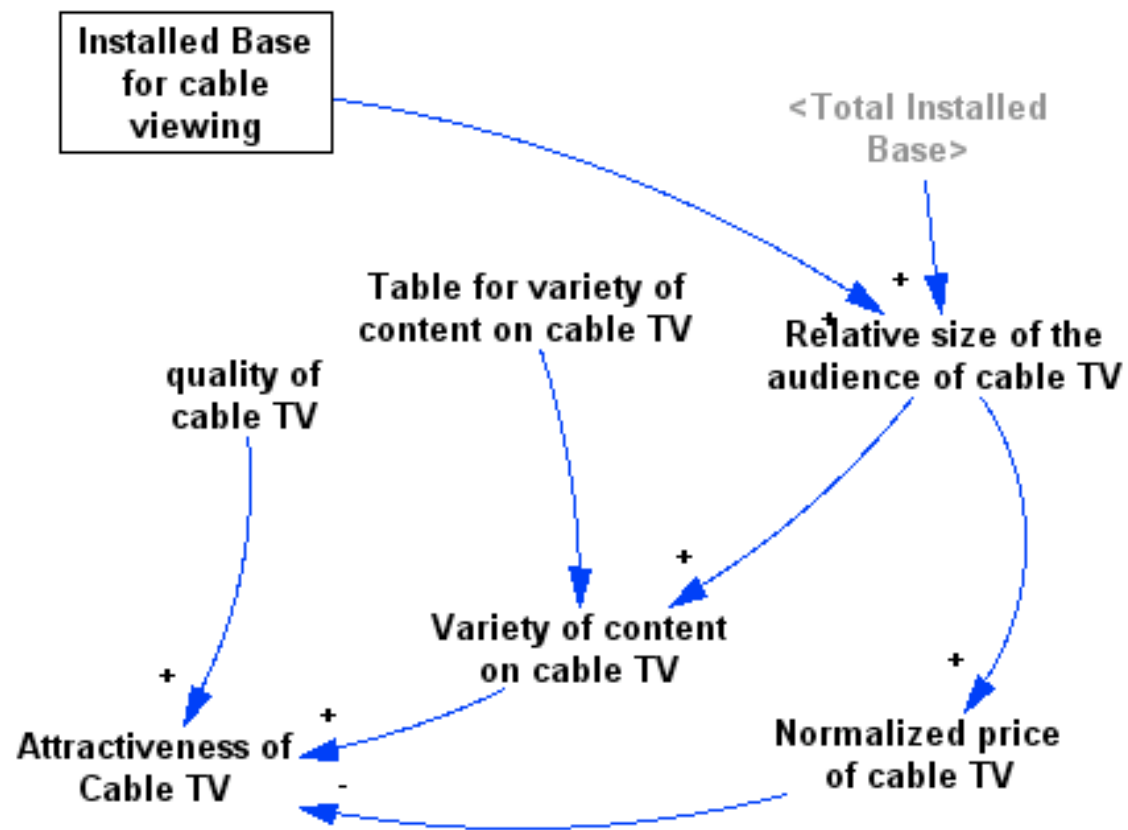

Table function for variety:

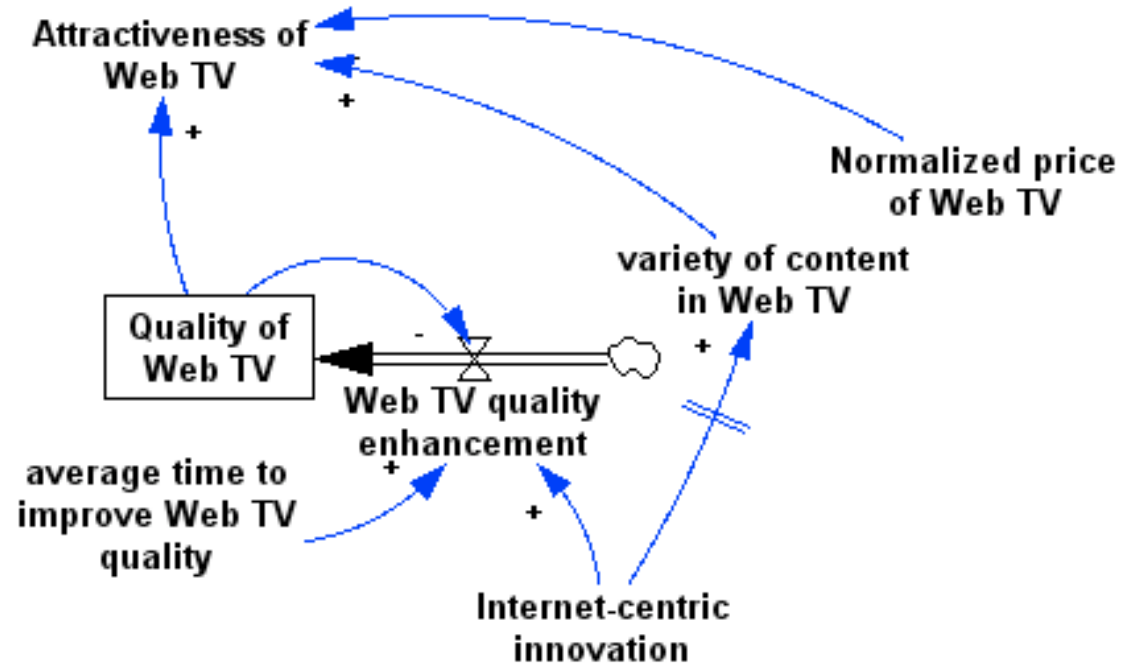

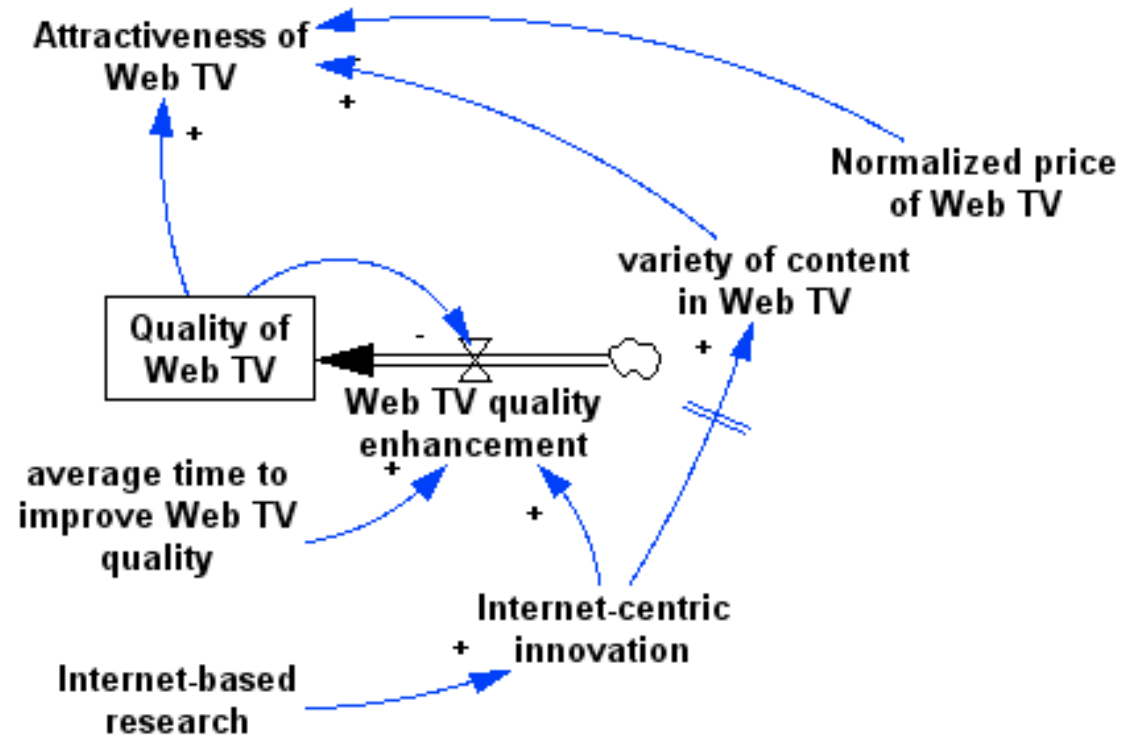

Dynamics of product adoption

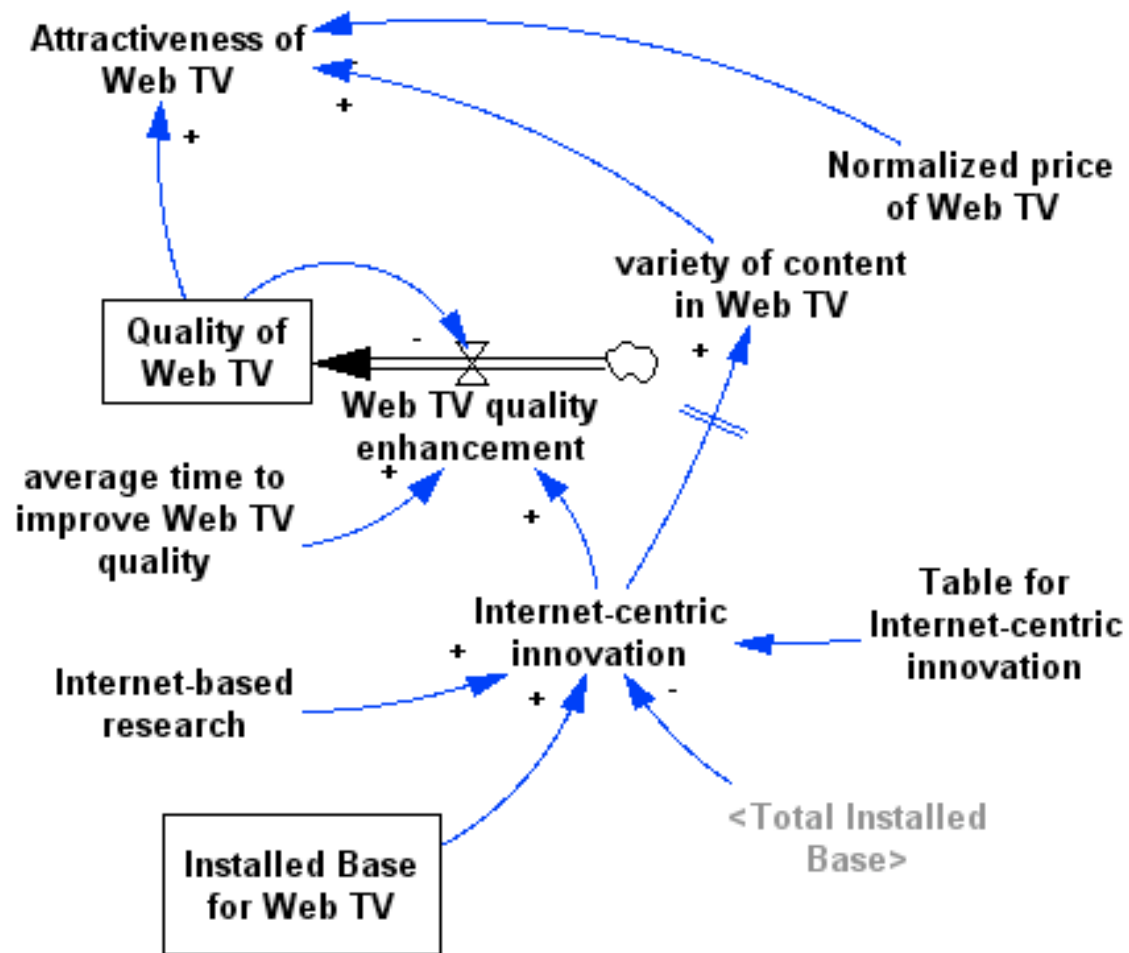

Hypotheses for Web TV:

- Cable is a fast growing technology
Quality driven by “Internet-based innovation”
- Variety of content varies quickly as capacity allows it
- Price for now is fixed, and above the current price of cable TV

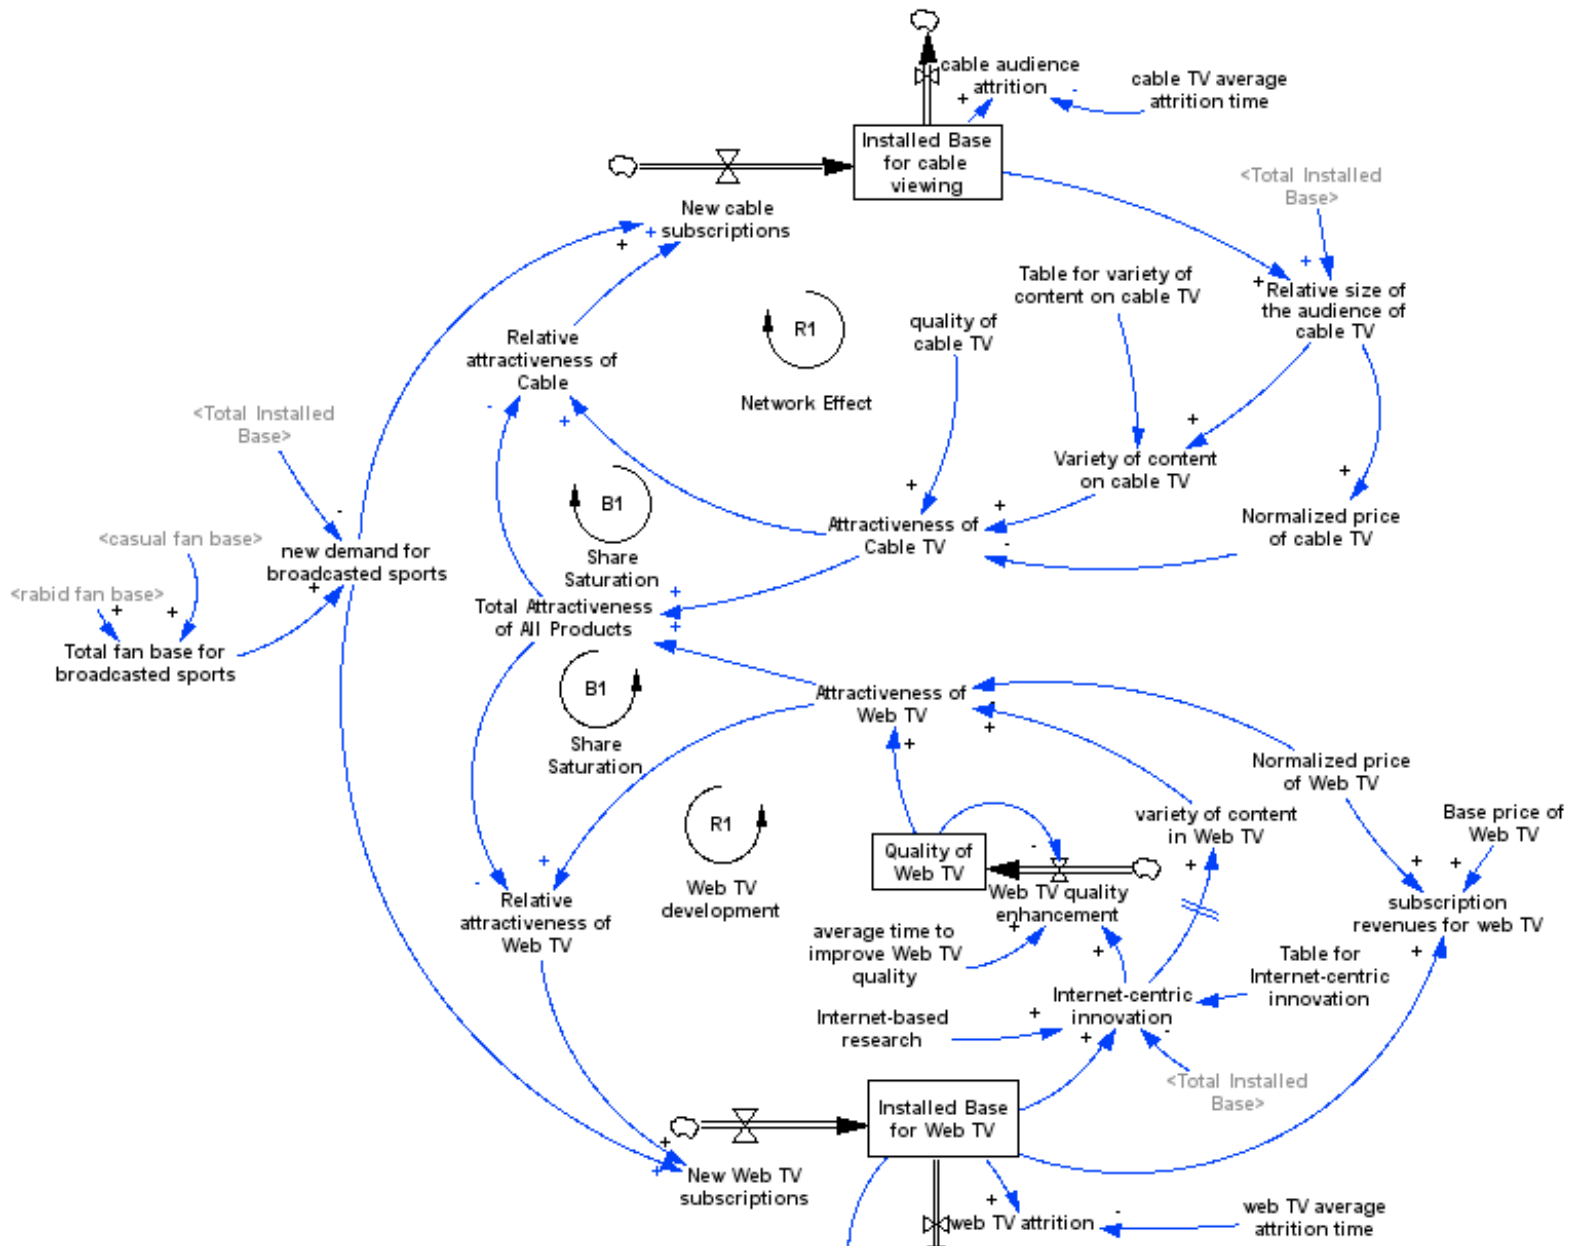

Dynamics of product adoption

Results as of today: compared qualities
